# Assignment 10 + Conditional Random Fields (SNLP tutorial 11)

Vilém Zouhar, Awantee Deshpande, Julius Steuer

6th, 8th July

# Organisation

- Check that you have the finalised versions of the tutorial slides (https://github.com/zouharvi/uds-snlp-tutorial/tree/main)
- Check if you are eligible for the exam, and register accordingly.
- Project will be released on Friday, expected deadline at the end of August (tentatively 20th Aug), will be specified in the project instructions.
- Next week's tutorial discussion: Open Q&A.
- Send a list of questions to me (Teams or Private Piazza Post) by Sunday, 11th July.
- Discussion of sample exam
- Other questions...?

# Assignment 10

- Exercise 1: Lesk's Algorithm
- Exercise 2: Expectation Maximisation
- Exercise 3: Yarowsky Algorithm

#### Overview

- Sequence Labelling / Entity Recognition
- Rule-based
- HMM
- Bayesian Network
- Log-linear 1st Order Sequential Model
- Linear Chain CRF / CRF
- Model comparison
- Implementations

# Sequence Labelling / Entity Recognition

- My name is John, I live in Saarbrücken, and my matriculation number is 1234.
- My name is [John:PERSON], I live in [Saarbrücken:LOC], and my matriculation number is [1234:MATNUM].
- NER as Sequence labelling:
  - X: sequence of words
  - Y: labels {MATNUM, PERSON, LOCATION, NONE}

a My name is John, I live in Saarbrücken, and my matriculation number is 1234. • My name is [John:PERSON], I live in [Saarbrücken:LOC], and my

matriculation number is [1234:MATNUM].

NER as Sequence labelling:

X: sequence of words

Y: labels (MATNUM, PERSON, LOCATION, NONE)

- NER can be reformulated as sequence labelling, which includes also e.g. part of speech tagging
- Given a sentence we want to classify every token.

#### Rule-based

• Regex substitute: matriculation (number)? (is)? (\d+) → [\3:mat-num]

- Gets out of hand quickly: (am|name (is)?) (.\*?) (and|\s[.,?])? → [\3:person]
- No automated learning

Assignment 10 + Conditional Random Fields

Roger substitute matriculation (comber)? (ia)? (\d+)  $\rightarrow$  [\3:mat-num] of the quickly. (as |max=[137], (.\*) (and |\ar\_1,7])?  $\rightarrow$  [\3:person] No automated Marning

Rule-based

 $\square$ Rule-based

- The most straightforward solution just uses regex substitution, but that becomes very complex very soon and is also not performant enough, because it does not learn from the data.
- The only advantage is that we know explicitly which rules get applied.
- Still bad in general.

### Generative vs. Discriminative Models

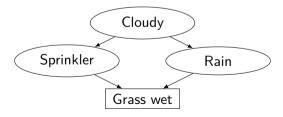

- Generative: Model actual distribution of data, learn joint probability and predict conditional probability using Bayes Theorem i.e. predict P(Y|X) using P(X|Y) and P(Y) e.g. Naive Bayes, HMMs
- Discriminative: Model decision boundary between classes, learn conditional probability directly, estimate parameters for P(Y|X) directly from data e.g. MaxEnt Classifier, CRFs

# Bayesian Network

• DAG,  $(x \rightarrow y) \in E : y$  dependent on x

### Local Markov Property

- Node is conditionally independent of its nondescendants given its parents. p(Sprinkler|Cloudy, Rain) = p(Sprinkler|Cloudy)
- How does this benefit us?

—Bayesian Network

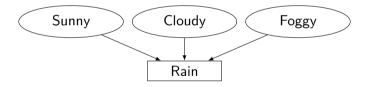

- Has to be DAG, otherwise cycles
- It models dependence between variables which can be either latent or observed
- We use it to reason about events of which we know the observed values and we want to know the cause
- From the graph we may for example find out, that it makes no sense to condition *Sprinkler* on *Rain*, because these two variables are independent. It would however be an approximation if we treated *Cloudy* independent of *Grass wet*.

# Naïve Bayes

• Assume absolute independence except for the one observed variable

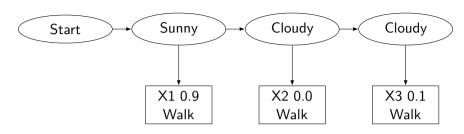

• 
$$p(y = \text{Yes}|x) = p(y_j|x) = \frac{p(x|y_j)p(y_j)}{p(x)} \propto p(x|y_j)p(y_j) \approx p(y_j)\prod_i p(x_i|y_j)$$

└─Naïve Bayes

- In Naïve Bayes we artificially flatten the network so that the observed variable is directly dependent to all causes and there are no other dependencies.
- The formula shows where the approximation is taking place.
- A practical example why this is naïve is that the variable Rain is heavily dependent on the Cloudy variable but as well on the Foggy, which in turn is almost the same thing as Cloudy.
   And if we put both all these in the formula, then we assign higher weight to the concept of cloudiness than to sunniness.

### **HMM**

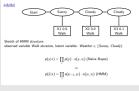

Sketch of HMM structure observed variable  $Walk\ duration$ , latent variable:  $Weather \in \{Sunny,\ Cloudy\}$ 

$$p(y|x) = \prod_{i} p(y) \cdot o(y, x_{i})$$
 (Naïve Bayes)  $\Rightarrow$   $p(\bar{y}|x) = \prod_{i} a(y_{i-1}, y_{i}) \cdot o(y_{i}, x_{i})$  (HMM)

Assignment 10 + Conditional Random Fields

<u></u>НММ

- From bayesian network point of view, HMMs model a structure in which latent variable is connected to another one, which in turn is connected to observed ones.
- These relationships are explicitly modeled by the transition (horizontal) and emission (vertical) functions.

# **HMM**

- Hidden states: {MATNUM, PERSON, LOCATION, NONE}
- Better hidden states: {MATNUM, START+PERSON, INTERNAL+PERSON, END+PERSON, LOCATION, NONE, ...}
- Transitions: MLE from annotated data
- Emission probabilities: MLE from annotated data (+ smoothing)
- $p(x,y) = \prod_i a(y_{i-1},y_i) \cdot o(y_i,x_i)$

### Questions

• What are the drawbacks of HMMs?

Assignment 10 + Conditional Random Fields

MMH-

a Hidden states: (MATNUM, PERSON, LOCATION, NONE) . Better hidden states: {MATNUM, START+PERSON, INTERNAL+PERSON, END+PERSON LOCATION, NONE, ... Transitions: MLE from annotated data . Emission probabilities: MLE from annotated data (+ smoothing) •  $p(x, y) = \prod_i a(y_{i-1}, y_i) \cdot o(y_i, x_i)$ . What are the drawbacks of HMMs?

LIMANA

- HMMs seem a better fit for this task, since it captures transition probabilities between latent variables and emission probabilities.
- The probability of the sequence is computed as the product of transitions and observations.
- The probabilities can be estimated using MLE counting + some smoothing
- Side note, HMM is a generative model, because it can model the joint distribution p(v,x)
- In case we don't have annotated data, we may still make use of HMMs by employing the Baum-Welch algorithm.
- The emission probabilities are just distributions over all observable variables and every latent variable gets a unique one. For example in POS tagging, it may be the partial counts, but in speech processing, it's a gaussian mixture.
- We usually require supervised examples to do this MLE counting, but the Baum-Welch algorithm is able to estimate all these probabilities even if we don't know the latent labels.
- The reason for low performance is that the emission probabilities capture only features that dependent only on the current state and we have little control over the features.

# Log-linear 1st Order Sequential Model

- Sequence of hidden states: y, {MATNUM, PERSON, LOCATION, NONE}
- Observed sequence of variables: x (words)
- Goal: Model p(y|x) for all pairs (x, y)
- $p(y|x) \propto \exp \left\{ \sum_{i} \log a(y_{i-1}, y_i) + \log o(y_i, x_i) \right\}$
- $p(y|x) = \frac{1}{Z(x)} \cdot \exp \{ \sum_{i} \log a(y_{i-1}, y_i) + \log o(y_i, x_i) \}$
- $p(y|x) = \frac{1}{Z(x)} \cdot \prod_i \exp\{a(y_{i-1}, y_i)o(y_i, x_i)\}$

Log-linear 1st Order Sequential Model

- # Sequence of hidden states: v. (MATNUM, PERSON, LOCATION, NONE) Observed senuence of variables: v (words) Goal: Model p(v|x) for all pairs (x,v)
- $\mathbf{z} \cdot \rho(\mathbf{v}|\mathbf{x}) \propto \exp \left\{ \nabla \cdot \log \rho(\mathbf{v}_{-1}, \mathbf{v}) + \log \rho(\mathbf{v}_{-1}, \mathbf{x}) \right\}$
- $p(y|x) = \frac{1}{2(x)} \cdot exp\{\sum_i \log a(y_{i-1}, y_i) + \log o(y_i, x_i)\}$
- $p(y|x) = \frac{1}{2(x)} \cdot \prod_{i} \exp\{a(y_{i-1}, y_{i})o(y_{i}, x_{i})\}$

Looks like HMM.

Log-linear 1st Order Sequential Model

This has exactly the same number of parameters but they all model p(y|x) and not p(x,y). This is more ideal for us.

# Log-linear 1st Order Sequential Model

- Replace  $o(y_j, x_t)$  with  $\lambda_1 h_1(y_j, x_t) + \lambda_2 h_2(y_j, x_t) + \dots$
- Same with  $a(y_j,y_i)=\lambda_1'g_1(y_j,y_i)+\lambda_2'g_2(y_j,y_i)+\dots$
- Why not just  $\sum_{\text{feature } f} \lambda_i f_i(y_i, y_j, x_t)$  ?

- Log-linear 1st Order Sequential Model
- o can be any scoring function, does not need to be a distribution like with HMMs
- It can be a sum of other feature functions.
- In fact, this can be generalized even further
- And finally, there is no reason to not allow features to observe the whole sequence, because neither Viterbi nor Forward decoding limits this.

#### Model overview

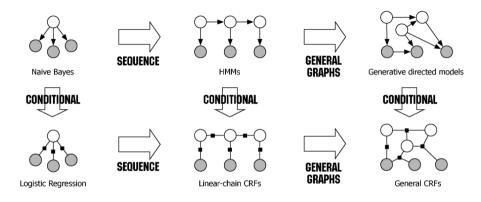

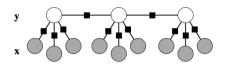

Figure 1: CRF in relation to other models; Source [2]

- There is a system of models with different properties.
- First, there is naive bayes and the conditional version, multinomial logistic regression.
- These model single class predictions. While naive bayes does this generatively, logistic regression uses the scoring mechanism.
- On sequences, we can either have the HMMs or a conditional version, which are linear chain CRFs.
- Finally there are models for which there is no clear correspondence between a latent variable and a single observed one.

#### HMM → Linear CRF

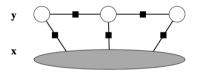

Figure 2: HMM vs. Linear Chain CRF; Source [12]

#### Question

• What is the difference between HMM and CRE?

# Conditional Random Fields

- Factorization to maximal cliques.
- Allow access to a whole clique

# Clique

$$G = (V, E)$$
  $C \subseteq V : \forall x, y \in C : (x, y) \in E$   $C \subseteq C' \Rightarrow C = C'$ 

#### **CRF**

$$p(y|x) = \frac{1}{Z(x)} \prod_{c \in C} \Psi_c(x_c)$$

# Maximal Clique

$$C \subseteq C' \Rightarrow C = C'$$

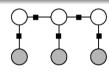

Figure 3: Linear CRF [2]

└─Conditional Random Fields

- We may generalize CRFs to allow access to more data in the feature functions
- This requires the graph to be factorized into maximal cliques on which we define the potential function
- Linear Chain CRFs fulfil these requirements, because they form a chain of latent variables, so maximal cliques are single nodes
- Explain cliques
- There is just a single decomposition into maximal clicque and it creates a factorization of the whole graph

# Linear CRF

- Sequence of hidden states: y, {MATNUM, PERSON, LOCATION, NONE}
- Observed sequence of variables: x (words)
- $p(y|x) \propto \prod_i \exp \left\{ \sum_j \lambda_j f_j(y_{i-1}, y_i, x, i) \right\}$
- $p(y|x) = \frac{1}{Z(x)} \prod_{i} \exp \left\{ \sum_{j} \lambda_{j} f_{j}(y_{i-1}, y_{i}, x, i) \right\}$
- Features:  $f_i(y_{i-1}, y_i, x, i)$
- ullet Parameters:  $\lambda$
- Clique template:  $\{\Psi_i(y_{i-1}, y_i, x, i) | \forall i \in \{1...n\}\}$

-Linear CRF

a Sequence of hidden states: v. (MATNUM, PERSON, LOCATION, NONE) Observed sequence of variables: x (words)  $p(y|x) \propto \prod_i \exp \{ \sum_i \lambda_i f_i(y_{i-1}, y_i, x, i) \}$ •  $p(y|x) = \frac{1}{f(x)} \prod_{i} \exp \{ \sum_{i} \lambda_{j} f_{j}(y_{i-1}, y_{i}, x, i) \}$ Features fi(v. 1. v. x. i) A Parameters: 1 • Clique template:  $\{\Psi_i(v_{i-1}, v_i, x_i, i) | \forall i \in \{1...n\}\}$ 

Linear CRE

- From the formulation we can see that it's again a discriminative model.
- The right side is not a probability, but rather a score, so we need to normalize it.
- Z, is the partition function for normalization (just like in softmax)

# Linear CRF - Binary Features

$$f_j(y_{i-1}, y_i, x, i) = \begin{cases} 1 & \text{if } cond_f(y_{i-1}, y_i, x, i) \\ 0 & \text{else} \end{cases}$$

$$f_1(y_{i-1},y_i,x,i) = egin{cases} 1 & ext{if } x_{i-2} ext{ is capitalized} \ 0 & ext{else} \end{cases}$$
 $f_a(y_{i-1},y_i,x,i) = egin{cases} 1 & ext{if } y_{i-1} = ext{number} \wedge y_t = ext{none} \ 0 & ext{else} \end{cases}$ 
 $\lambda_a = a( ext{number}, ext{none})$ 
 $f_o(y_{i-1},y_i,x,i) = egin{cases} 1 & ext{if } y_i = ext{number} \wedge x_i = < ext{num} > \ 0 & ext{else} \end{cases}$ 
 $\lambda_a = o( ext{number}, < ext{num} >)$ 

Linear CRF - Binary Features

- The feature functions here are indicators, that produce 1 in case of some conditions.
- These conditions have access to the current and the last latent variable, but also to all observed variables and the current position.
- This way we can emulate the log-linear 1st order sequential model by using these indicator functions and setting the corresponding variables.
- The theta parameters are learnable from the data.

# Linear Chain CRF - Non-binary Features

$$f_w(y_{i-1},y_i,x,i)=|x_i|$$
 word length  $f_s(y_{i-1},y_i,x,i)=|c|$  number of non-alphabetic characters

# Questions

- How do we interpret the values of  $\lambda_i$  for the features  $f_i$ ?  $(\lambda_i > 0, \lambda_i = 0, \lambda_i < 0?)$
- How are  $\lambda$ s estimated?
- How many such features can we create?

Assignment 10 + Conditional Random Fields

Linear Chain CRF - Non-binary Features

Linear Chain CRF – Non-binary Features  $\{ \ell_1(y_1,y_2,x_3), x_4, x_5\} = |x_5| \text{ word largely}$   $\{ \ell_2(y_2,y_2,x_3), x_5\} = |x_5| \text{ worder of non-alphabetic characters}$  Commons.  $\{ k_1, k_2, k_3, x_5\} = |x_5| \text{ worder of } k_3 \text{ for the features } \{ \ell_1 \setminus y_5 = 0, \lambda_2 = 0, \lambda_3 < 0 \}$  where  $k_1$  is a destinated?  $k_2 = k_3 \text{ the many with destinates was we caused?}$ 

- In CRFs it is common to have an order of thousands features
- Multiple features can be active for a certain sequence and so, CRFs tend to overlap features, which HMMs cannot do.

# **CRF** - Operations

Training:

$$argmax_{\lambda} p(y_D|x_D, \lambda)$$

Interpretation: Given label sequences and inputs, find parameters of the CRF M that maximise  $p(y|x,\lambda)$ .

Done using gradient methods, Forward-Backward algorithm etc.

Inference:

$$argmax_y p(y|x,\lambda)$$

Decoding:

$$\max p(y|x,\lambda)$$

Interpretation: Given input x and CRF M, find optimal y. Done using Viterbi algorithm.

Assignment 10 + Conditional Random Fields

CRF - Operations

- Inference viterbi
- Decoding forward
- Training gradient methods

# CRF - Operations Training $agman, p(r_0)r_0.1$ ) Interpretation: Given liabil sequences and inputs, find parameters of the CRF M that maximize $f(r_0)r_0.1$ to always gradient methods, forward-Blackward algorithm etc. Inference: $agman, p(r_0)r_0.1$ ) Describe: $agman, p(r_0)r_0.1$ )

Interpretation: Given input x and CRF M, find optimal y.

#### Feature selection:

#### Alternative 1

- Start with all features.
- 4 If there exists a feature removing which worsens the performance by < t, remove it. Repeat 2.
- If not, exit.

#### Alternative 2

- Start with no features.
- 4 If there exists a feature adding which improves the performance by > t, add it. Repeat 2.
- If not, exit.

#### **Properties**

- Hard to setup & train
- Fast inference

Assignment 10 + Conditional Random Fields

Feature selection:

Some on the Enters.

Some of the Enters.

Feature selection:

- In practice, one may also wish to use just a limited number of features.
- When adding, it is possible to consider also combining with existing features. Especially for indicator features, it is possible to combine them using boolean operators.
- This can also be done in reverse remove least useful features.

# Linear Chain CRF - Regularization

Objective function:

$$\mathcal{L} = \sum_{s} \log p(y^{(s)}|x^{(s)},\lambda)$$

LASSO:

$$\mathcal{L}_{+lasso} = \sum_{s} \log p(y^{(s)}|x^{(s)},\lambda) - \lambda_1 \sum_{i} |\lambda_i|$$

Ridge:

$$\mathcal{L}_{+\textit{ridge}} = \sum_{s} \log p(y^{(s)}|x^{(s)},\lambda) - \frac{\lambda_2}{2} \sum_{i} \lambda_i^2$$

Elastic net:

$$\mathcal{L}_{+elastic} = \sum_{s} \log p(y^{(s)}|x^{(s)}\lambda) - \frac{\lambda_2}{2} \sum_{i} \lambda_i^2 - \lambda_1 \sum_{i} |\lambda_i|$$

# Code

```
from sklearn_crfsuite import CRF
X_train = [
     [word2features(s, i) for i in range(len(s))]
     for s in train_sents]
y_train = [
      [label for token, postag, label in s]
         for s in train_sents]

crf = sklearn_crfsuite.CRF(
        algorithm='lbfgs',
        c1=0.1, c2=0.1,
        max_iterations=100,
)
crf.fit(X_train, y_train)
```
